

Photo Caption: Above are brain scans using PET technology.

What are PET scans? Positron Emission Tomography scans show cellular function. They glow the brightest where the cells react the most to a radioactive form of glucose injected into the bloodstream.

What are they used for? Detecting cancer, analyzing heart health, and brain-related disorders like Alzheimer's Disease.

Why not an MRI or X-Ray? PET scans show cellular activity, while MRIs and X-Rays show structure, like the sizes and shapes of bones, tissue, and organs.

Can they determine someone's personality? No. It is speculative. There is no scientific evidence that establishes a causal effect between specific cellular activities in the brain to personal character traits.
